

Introduction to Machine Learning

Homework 8: Convolutional Neural Networks

Prof. Sundeep Rangan

Submit answers to only problems 1–3. But, make sure you know how to do all problems.

1. Let X and W be arrays,

$$X = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 3 & 3 & 3 & 0 \\ 0 & 3 & 3 & 3 & 0 \\ 0 & 3 & 2 & 3 & 0 \\ 0 & 3 & 2 & 3 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \quad W = \begin{bmatrix} 1 & -1 \\ 1 & -1 \end{bmatrix}.$$

Let Z be the 2D convolution (without reversal):

$$Z[i, j] = \sum_{k_1, k_2} W[k_1, k_2] X[i + k_1, j + k_2]. \quad (1)$$

Assume that the arrays are indexed starting at $(0, 0)$.

- (a) What are the limits of the summations over k_1 and k_2 in (1)?
 - (b) What is the size of the output $Z[i, j]$ if the convolution is computed only on the *valid* pixels (i.e. the pixel locations (i, j) where the summation in (1) does not exceed the boundaries of W or X).
 - (c) What is the largest positive value of $Z[i, j]$ and state one pixel location (i, j) where that value occurs.
 - (d) What is the largest negative value of $Z[i, j]$ and state one pixel location (i, j) where that value occurs.
 - (e) Find one pixel location where $Z[i, j] = 0$.
2. Suppose that a convolutional layer of a neural network has an input tensor $X[i, j, k]$ and computes an output via a convolution and ReLU activation,

$$Z[i, j, m] = \sum_{k_1} \sum_{k_2} \sum_n W[k_1, k_2, n, m] X[i + k_1, j + k_2, n] + b[m],$$
$$U[i, j, m] = \max\{0, Z[i, j, m]\}.$$

for some weight kernel $W[k_1, k_2, n, m]$ and bias $b[m]$. Suppose that X has shape $(48, 64, 10)$ and W has shape $(3, 3, 10, 20)$. Assume the convolution is computed on the *valid* pixels.

- (a) What are the shapes of Z and U ?
 - (b) What are the number of input channels and output channels?
 - (c) How many multiplications must be performed to compute the convolution in that layer?
 - (d) If W and b are to be learned, what are the total number of trainable parameters in the layer?
3. Suppose that a convolutional layer in some neural network is described as a linear convolution followed by a sigmoid activation,

$$Z[i, j, m] = \sum_{k_1} \sum_{k_2} \sum_n W[k_1, k_2, n, m] X[i + k_1, j + k_2, n] + b[m],$$

$$U[i, j, m] = 1/(1 + \exp(-Z[i, j, m])).$$

where $X[i, j, n]$ is the input of the layer and $U[i, j, m]$ is the output. Suppose that during back-propagation, we have computed the gradient $\partial J/\partial U$ for some loss function J . That is, we have computed the components $\partial J/\partial U[i, j, m]$. Show how to compute the following:

- (a) The gradient components $\partial J/\partial Z[i, j, m]$.
 - (b) The gradient components $\partial J/\partial W[k_1, k_2, n, m]$.
 - (c) The gradient components $\partial J/\partial X[i, j, n]$.
4. In the previous problem, we considered a single sample. Suppose there were a mini-batch of samples.
- (a) How would you represent Z and U for the mini-batch case?
 - (b) Re-write the equations for Z and U .
 - (c) Re-compute the gradients.
